ORF307 – Optimization

21. Integer optimization algorithms

Bartolomeo Stellato — Spring 2024

Recap

Relaxations

Remove integrality constraints

minimize $\quad c^T x$

subject to $\quad Ax \le b$

$P_{\text{ip}} \longrightarrow \quad\quad x_i \in \mathbf{Z}, \quad i \in \mathcal{I}$

$\longrightarrow$
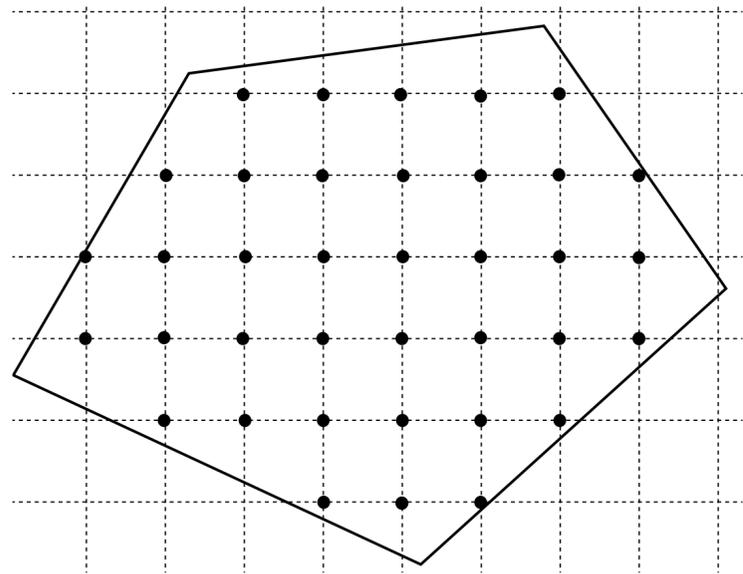

minimize $\quad c^T x$

subject to $\quad Ax \le b \quad \longleftarrow \quad P_{\text{rel}}$
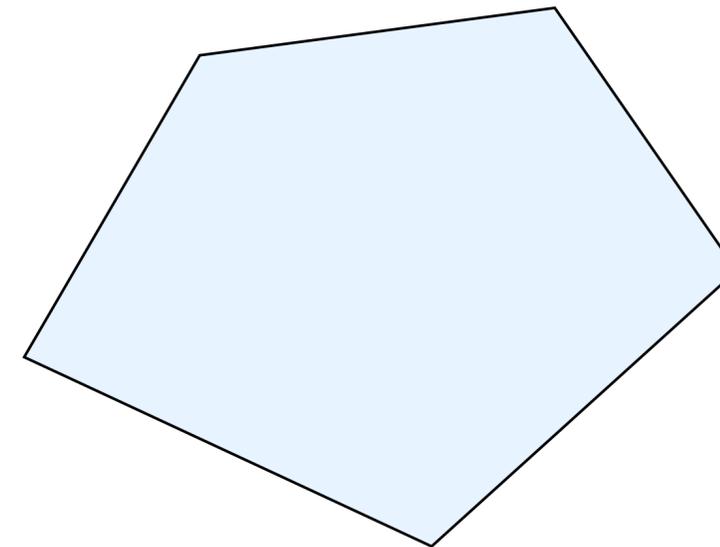

$P_{\text{ip}} \subset P_{\text{rel}} \quad \longrightarrow$ Relaxations provide **lower bounds** to $p_{\text{ip}}^\star$

$$p_{\text{rel}}^\star \le p_{\text{ip}}^\star$$

3

Ideal formulations

A formulation is ideal if solving its relaxation gives
an integer feasible point

minimize $\quad c^T x$

subject to $\quad Ax \leq b$

$\qquad x_i \in \mathbf{Z}, \quad i \in \mathcal{I}$

$\longrightarrow$

minimize $\quad c^T x$

subject to $\quad Ax \leq b$

$\longrightarrow$

integer feasible

$x^\star$
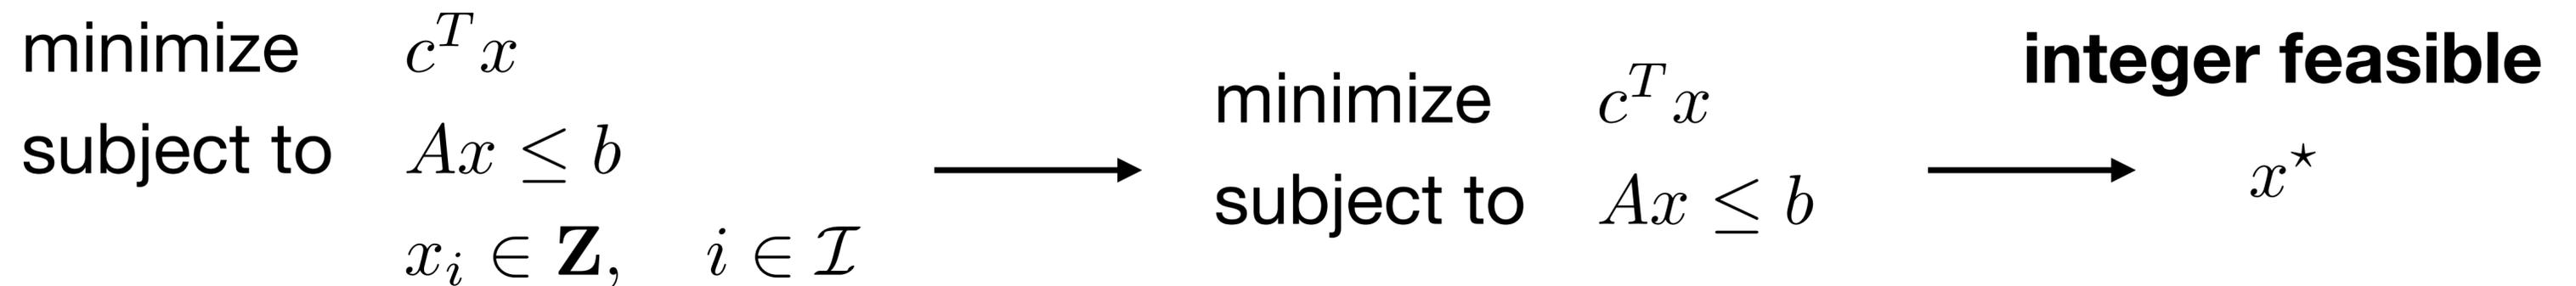

This happens if

$$\mathbf{conv}\, P = \{Ax \leq b\}$$
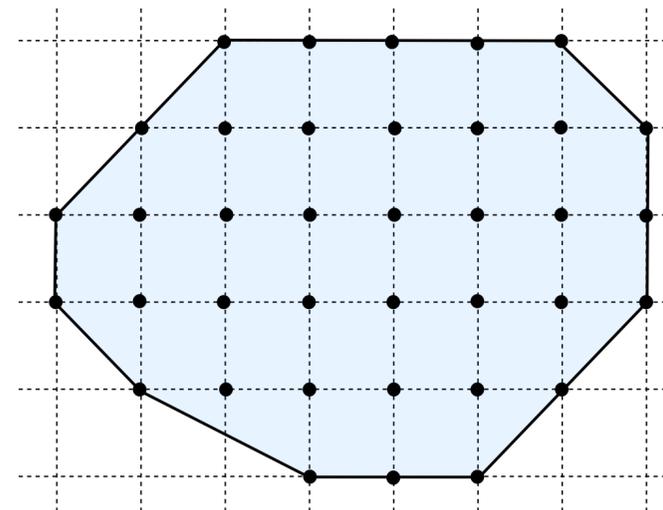

It is very hard to construct ideal formulations!

How do we solve integer optimization problems?

minimize $\quad c^T x$

subject to $\quad Ax \le b$

$\qquad\qquad x_i \in \mathbf{Z}, \quad i \in \mathcal{I}$
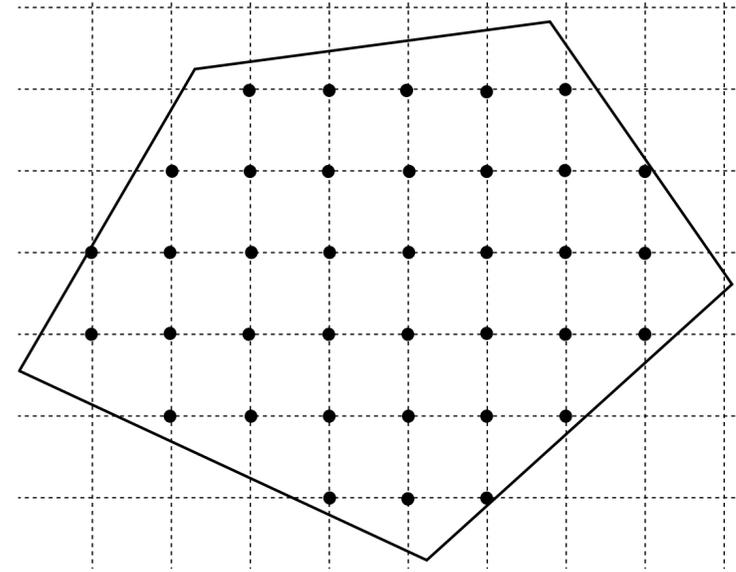

Main idea

Refine the feasible set until the relaxation
gives integer feasible solutions!

Today's lecture
Integer optimization algorithms

- Branch and bound algorithm

- Branch and bound rules

- Examples

- Cardinality minimization

Branch-and-bound algorithm

Example

$$\begin{aligned} \text{minimize} \quad & c^T x \\ \text{subject to} \quad & Ax \leq b \\ & x_1 \in \{0, 1\} \end{aligned}$$

How do you solve it?

$$\begin{aligned} \text{minimize} \quad & c^T x \\ \text{subject to} \quad & Ax \leq b \\ & x_i \in \{0, 1\}, \quad i = 1, \ldots, 10 \end{aligned}$$

- Solve $2^{10} = 1024$ LPs
- Parallelize solutions
- Warm-start: similar problems

It can quickly explode: $2^{30} \approx 1$ bln

Branch and bound works more systematically
and
(hopefully) decreases the number of subproblems

Branch and bound algorithm

minimize $\quad c^T x$

subject to $\quad x \in P_{\text{ip}}$

$$P_{\text{ip}} = \{x \mid Ax \leq b, \quad x_i \in \mathbf{Z}, \ i \in \mathcal{I}\}$$

Divide and conquer

- **Partition** P_{ip} in smaller sets S^j
- **Solve subproblems**

  minimize $\quad c^T x$

  subject to $\quad x \in S^j$

- Until **optimal** $x^\star$ **is found**
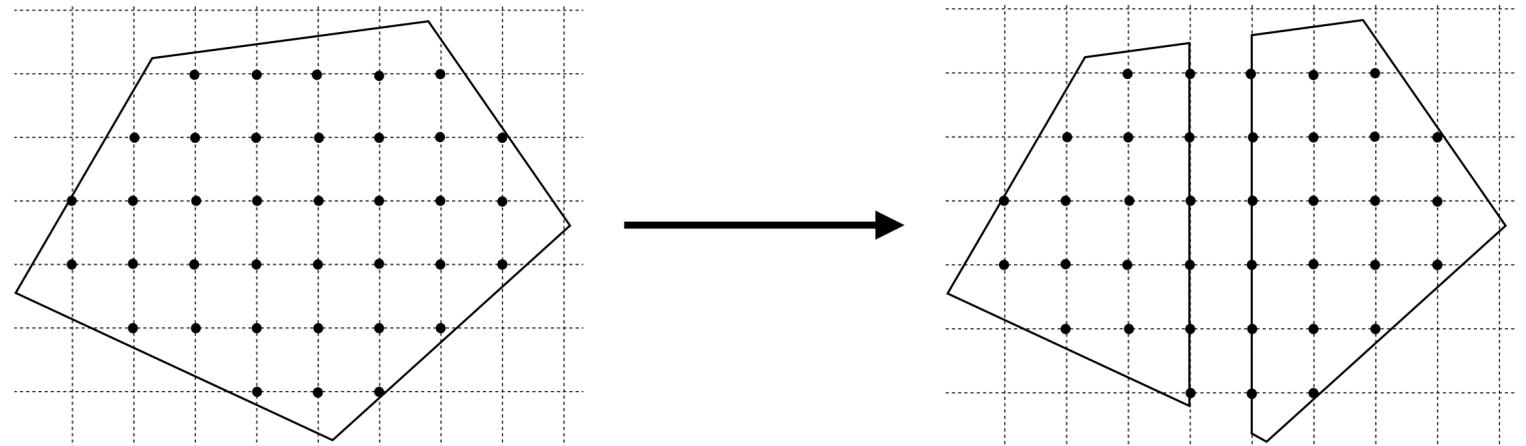

Two efficient subroutines

S^j

For every region S^j

$$\Phi(S^j) = \min_{x \in S^j} c^T x$$
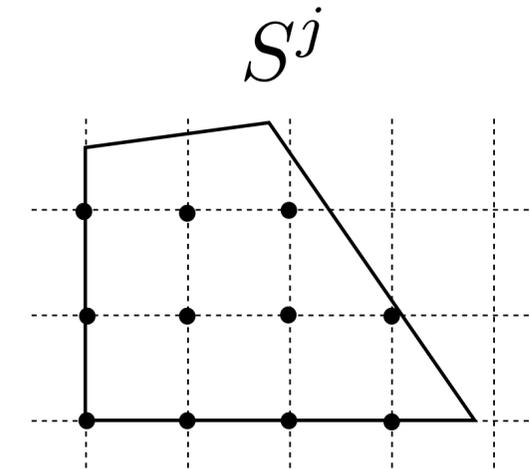

Lower and upper bounds
(they must be cheap to compute)

$$\Phi_{\mathrm{lb}}(S^j) \leq \Phi(S^j) \leq \Phi_{\mathrm{ub}}(S^j)$$

Lower bound
(relaxation)

Upper bound
(evaluate any point)

Bounds guide us in the search!

Branch and bound algorithm

minimize $\quad c^T x$

subject to $\quad x \in P_{\text{ip}}$

$$P_{\text{ip}} = \{x \mid Ax \le b, \quad x_i \in \mathbf{Z}, \; i \in \mathcal{I}\}$$

Iterations

1. **Branch**: create/refine the partition if P_{ip} and get S^j

2. **Bound:**
   - Compute **lower** and **upper bounds**
     $$L_j = \Phi_{\text{lb}}(S^j), \quad U_j = \Phi_{\text{ub}}(S^j), \quad \forall j$$
   - Update **global bounds** on $c^T x^\star$
     $$L = \min_j\{L_j\}, \quad U = \min_j\{U_j\}$$

3. If $U - L \le \epsilon$, **break**

Branch and bound
Example in 2D

P_{ip}

$U = 8.5$
$L = 2$

$S_1 \qquad S_2$
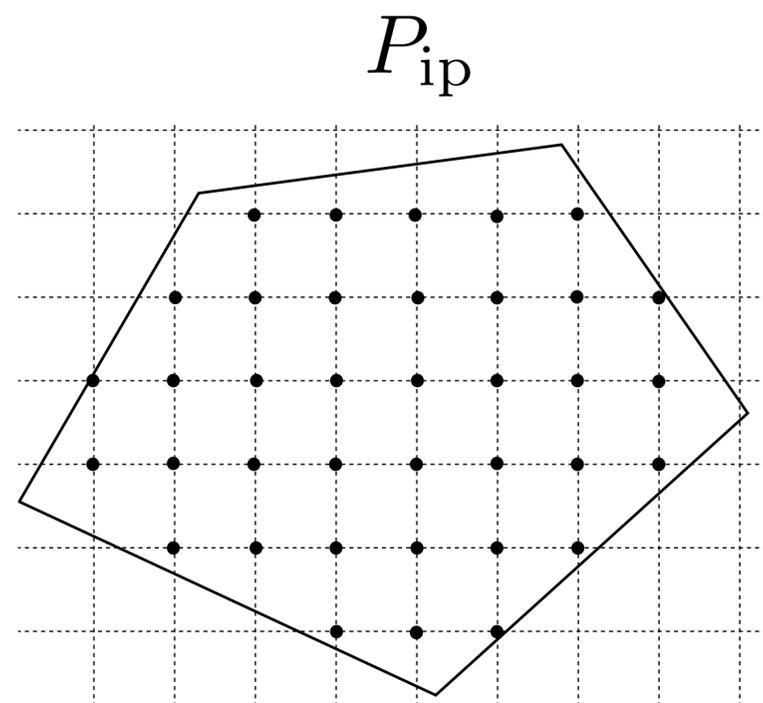

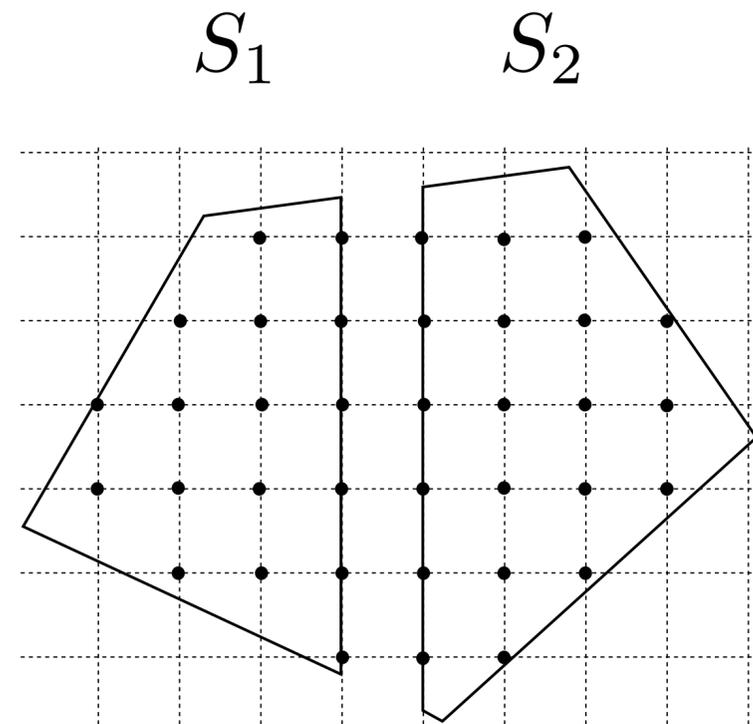

$U_1 = 8.5$ $U_2 = 4.2$
$L_1 = 6$ $L_2 = 2$

What does this say about global bounds L and U?

Partition as a binary tree
Example in 2D

Partition
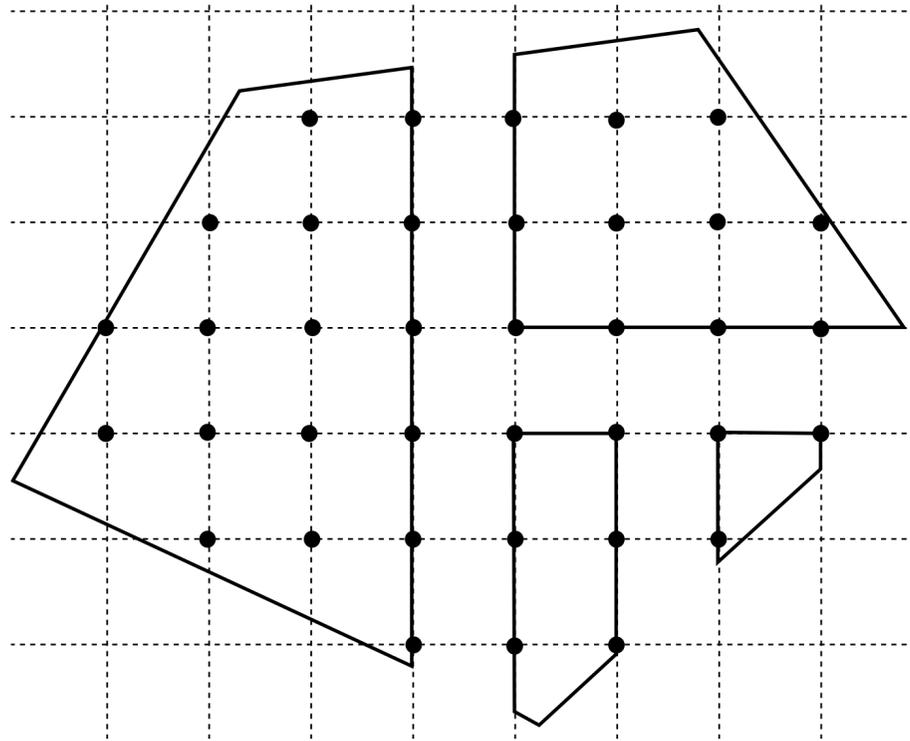

Binary tree
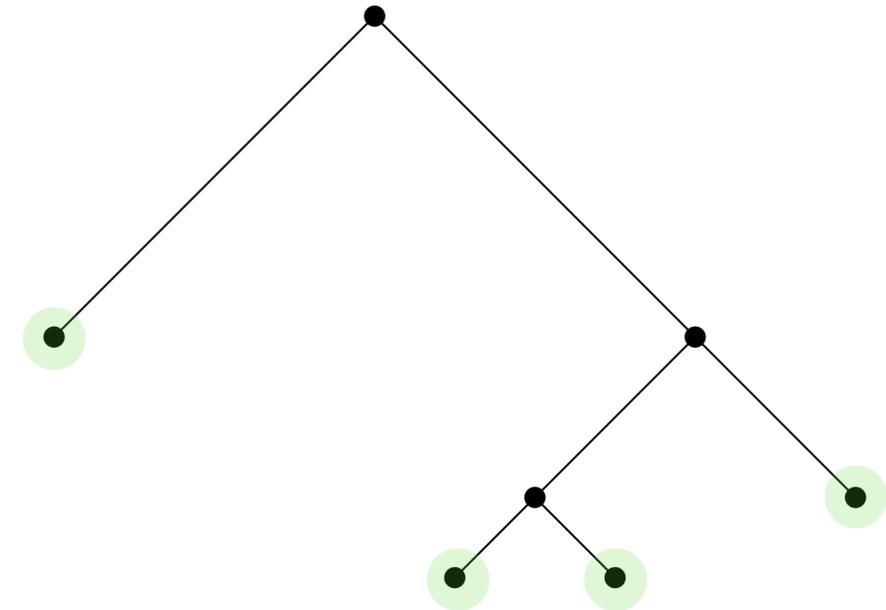

At each step we have a **binary tree**

Children correspond to subregions formed by splitting parents

Certifying optimality

certify optimality $\longrightarrow$ $L \leq c^T x^\star \leq U$ $\longleftarrow$ return feasible point "incumbent"

Partition = Leaves
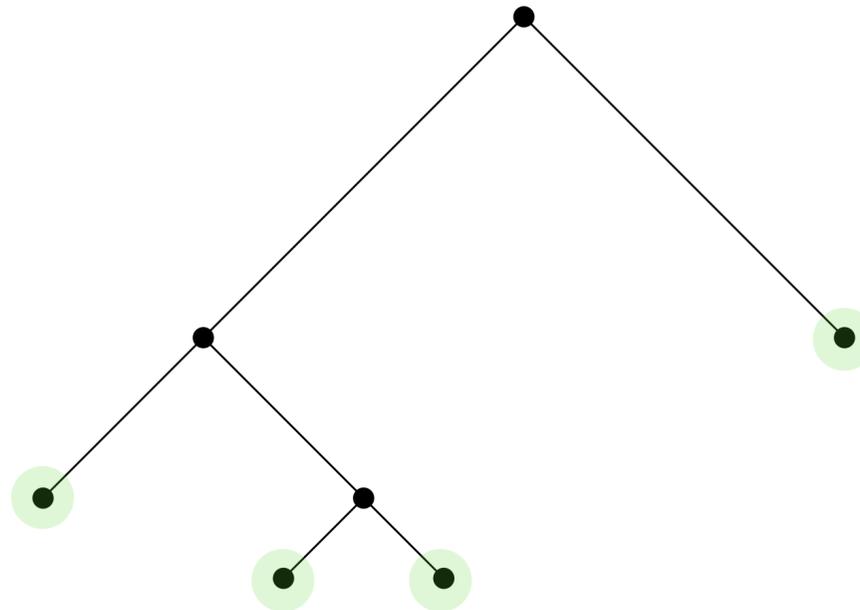

**Optimality certificate in integer optimization**

- Partition S^j
- Bounds $(L_j, U_j) \quad \forall j$

Optimality certificate in linear optimization

Dual variables and cost

14

Branch and bound rules

Partitioning
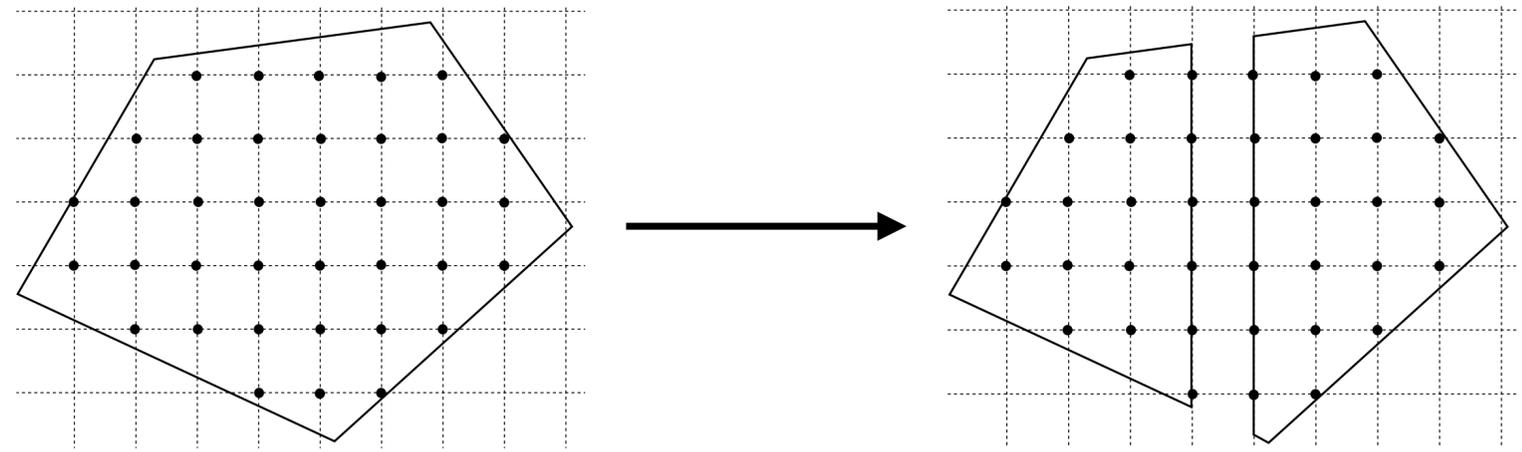

Pick one subproblem and solve its relaxation

$$\bar{x} \leftarrow \quad \text{minimize} \quad c^T x$$
$$\text{subject to} \quad x \in S^j_{\text{rel}}$$

Two possible outcomes

- If $\bar{x}$ integral ($\bar{x} \in S^j$), then $\bar{x}$ is the optimal solution to the subproblem

- If $\bar{x}$ is not integral, then there is an $\bar{x}_i$, $i \in \mathcal{I}$ that is fractional and **we partition**

Create two subproblems

$$\text{minimize} \quad c^T x$$
$$\text{subject to} \quad x \in S^j$$
$$x_i \leq \lfloor \bar{x}_i \rfloor$$

$$\text{minimize} \quad c^T x$$
$$\text{subject to} \quad x \in S^j$$
$$x_i \geq \lceil \bar{x}_i \rceil$$

16

Branching rules

Branching decisions
- Which region S^j to split
- Which fractional variable $\bar{x}_i$

Goal

Get tight global bounds as quickly as possible

They can **dramatically affect performance**

Example heuristic (best-bound search)
- **Optimism**: split S^j with lowest L_j
- **Greed**: split most fractional $\bar{x}_i$

Pruning

Key performance component

$$L = \min_j L_j \leq c^T x^\star \leq \min_j U_j = U$$

S^j is **active** if $L_j \leq \min_j U_j$

Otherwise it is **inactive** $(x^\star \notin S^j)$
and we can **prune** it

Questions

What is S^1? active/inactive

What is S_2? active/inactive

S_1 S_2

$U_1 = 10$ $U_2 = 4.2$
$L_1 = 6$ $L_2 = 1.5$
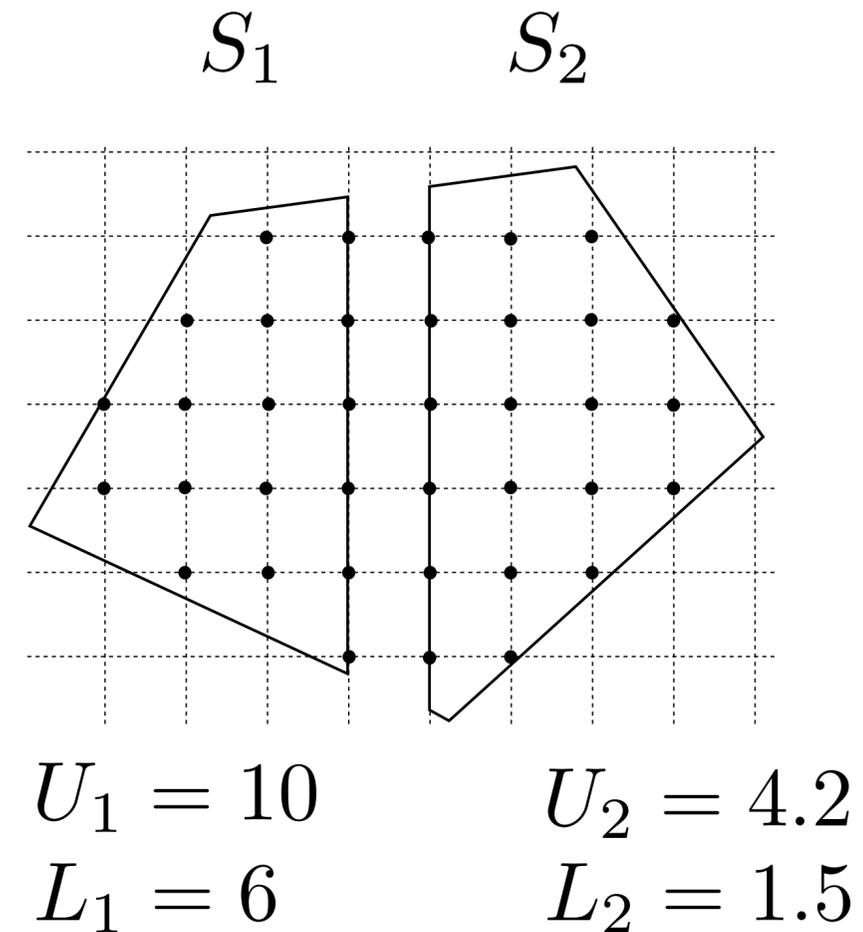

$L = L_2$
$U = U_2$

Bounding rules

Lower bounds. Solve relaxation

$$\bar{x} \leftarrow \quad \text{minimize} \quad c^T x$$
$$\text{subject to} \quad x \in S^j_{\text{rel}}$$

S^j

S^j_{rel}

- $L_j = c^T \bar{x}$
- $L_j = \infty$ if infeasible
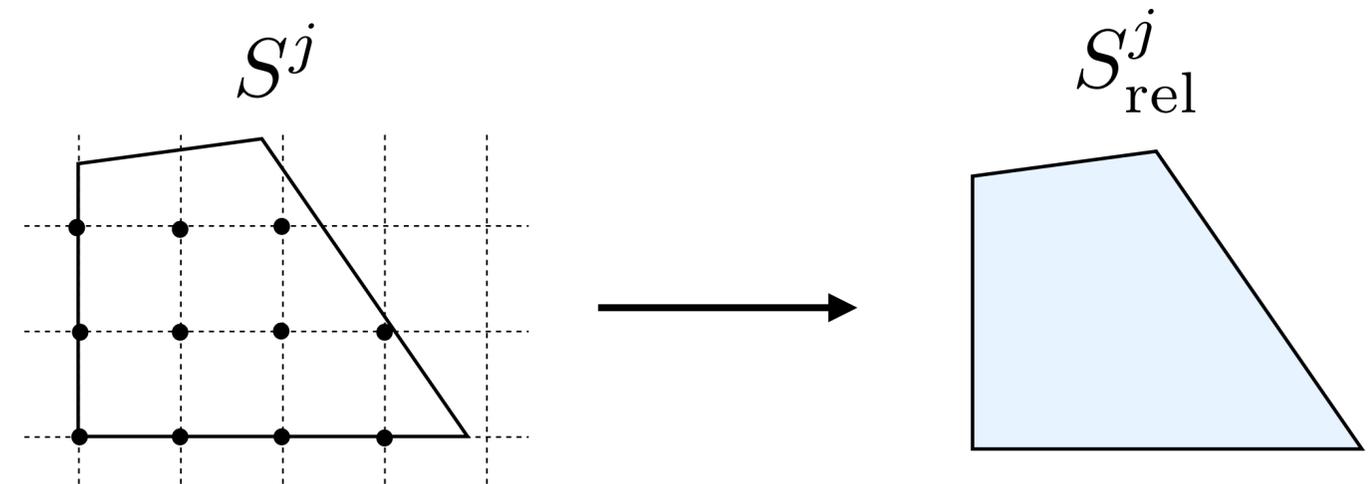

Upper bounds. Try to get feasible point

- $[\bar{x}] \leftarrow$ Round $\bar{x}$ (relaxation solution)
- $U_j = c^T [\bar{x}]$
- $U_j = \infty$ if $[\bar{x}] \notin S^j$ (not feasible)

Branch and bound convergence

minimize $\quad c^T x$

subject to $\quad Ax \le b$

$\qquad\qquad x \in \{0,1\}^n$

Example $x \in \mathbf{Z}^d$

Branch and bound

worst-case: we end up partitioning all 2^n points

hope: it works better for our problem

Brute force

Solve problem for all 2^n possible values of $x \in \{0,1\}^n$

(it blows up for $n \ge 20$)
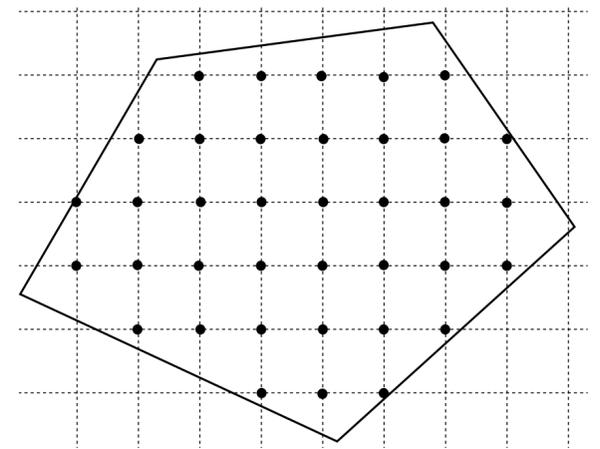

Practical considerations

Subproblem solutions are independent

We can solve them in parallel on multiple cores or computing nodes

Subproblems can be very similar
(feasible region with added constraints)

We can warm start the subproblem algorithm

Which algorithm would you use LP subproblems?

Small examples

Branch and bound example

minimize $-2x_1 - 3x_2$

subject to $(2/9)x_1 + (1/4)x_2 \leq 1$

$(1/7)x_1 + (1/3)x_2 \leq 1$

$x_1, x_2 \geq 0$

$x_1, x_2 \in \mathbf{Z}$

Optimal solution

$x^\star = (2, 2)$

Branch and bound example

x_2

$-c$

$[-10.55, -10]$
$\bar{x} = (2.17, 2.06)$

$x_1 \leq 2$

$x_1 \geq 3$

$[-10.43, -10]$
$\bar{x} = (2, 2.14)$

$x_2 \leq 2$

$x_2 \geq 3$

$[-10, -9]$
$\bar{x} = (3, 1.33)$

$[-10, -10]$
$\bar{x} = (2, 2)$

$[-9, -9]$
$\bar{x} = (0, 3)$

x_1
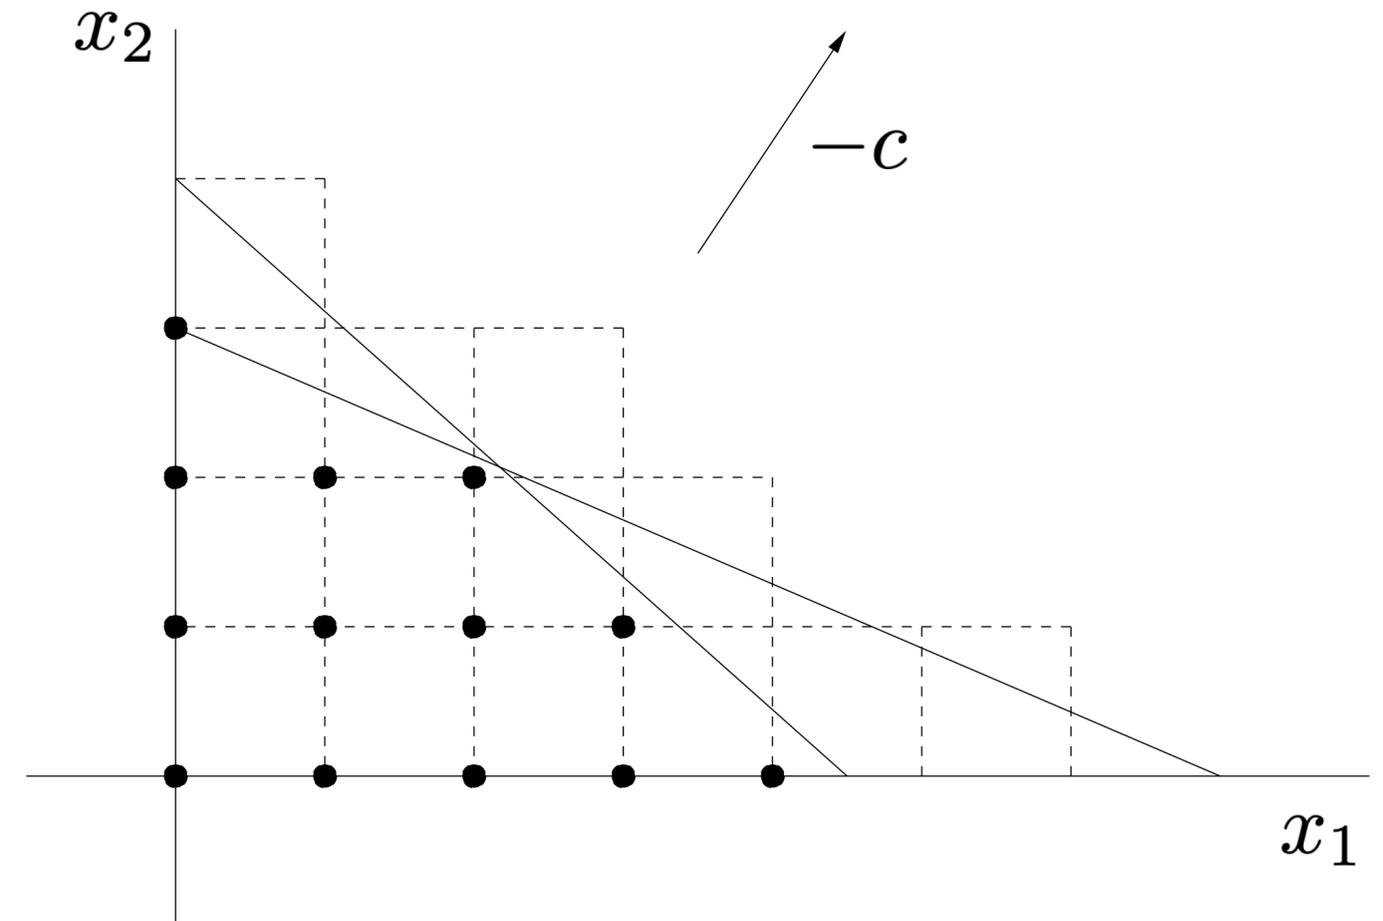

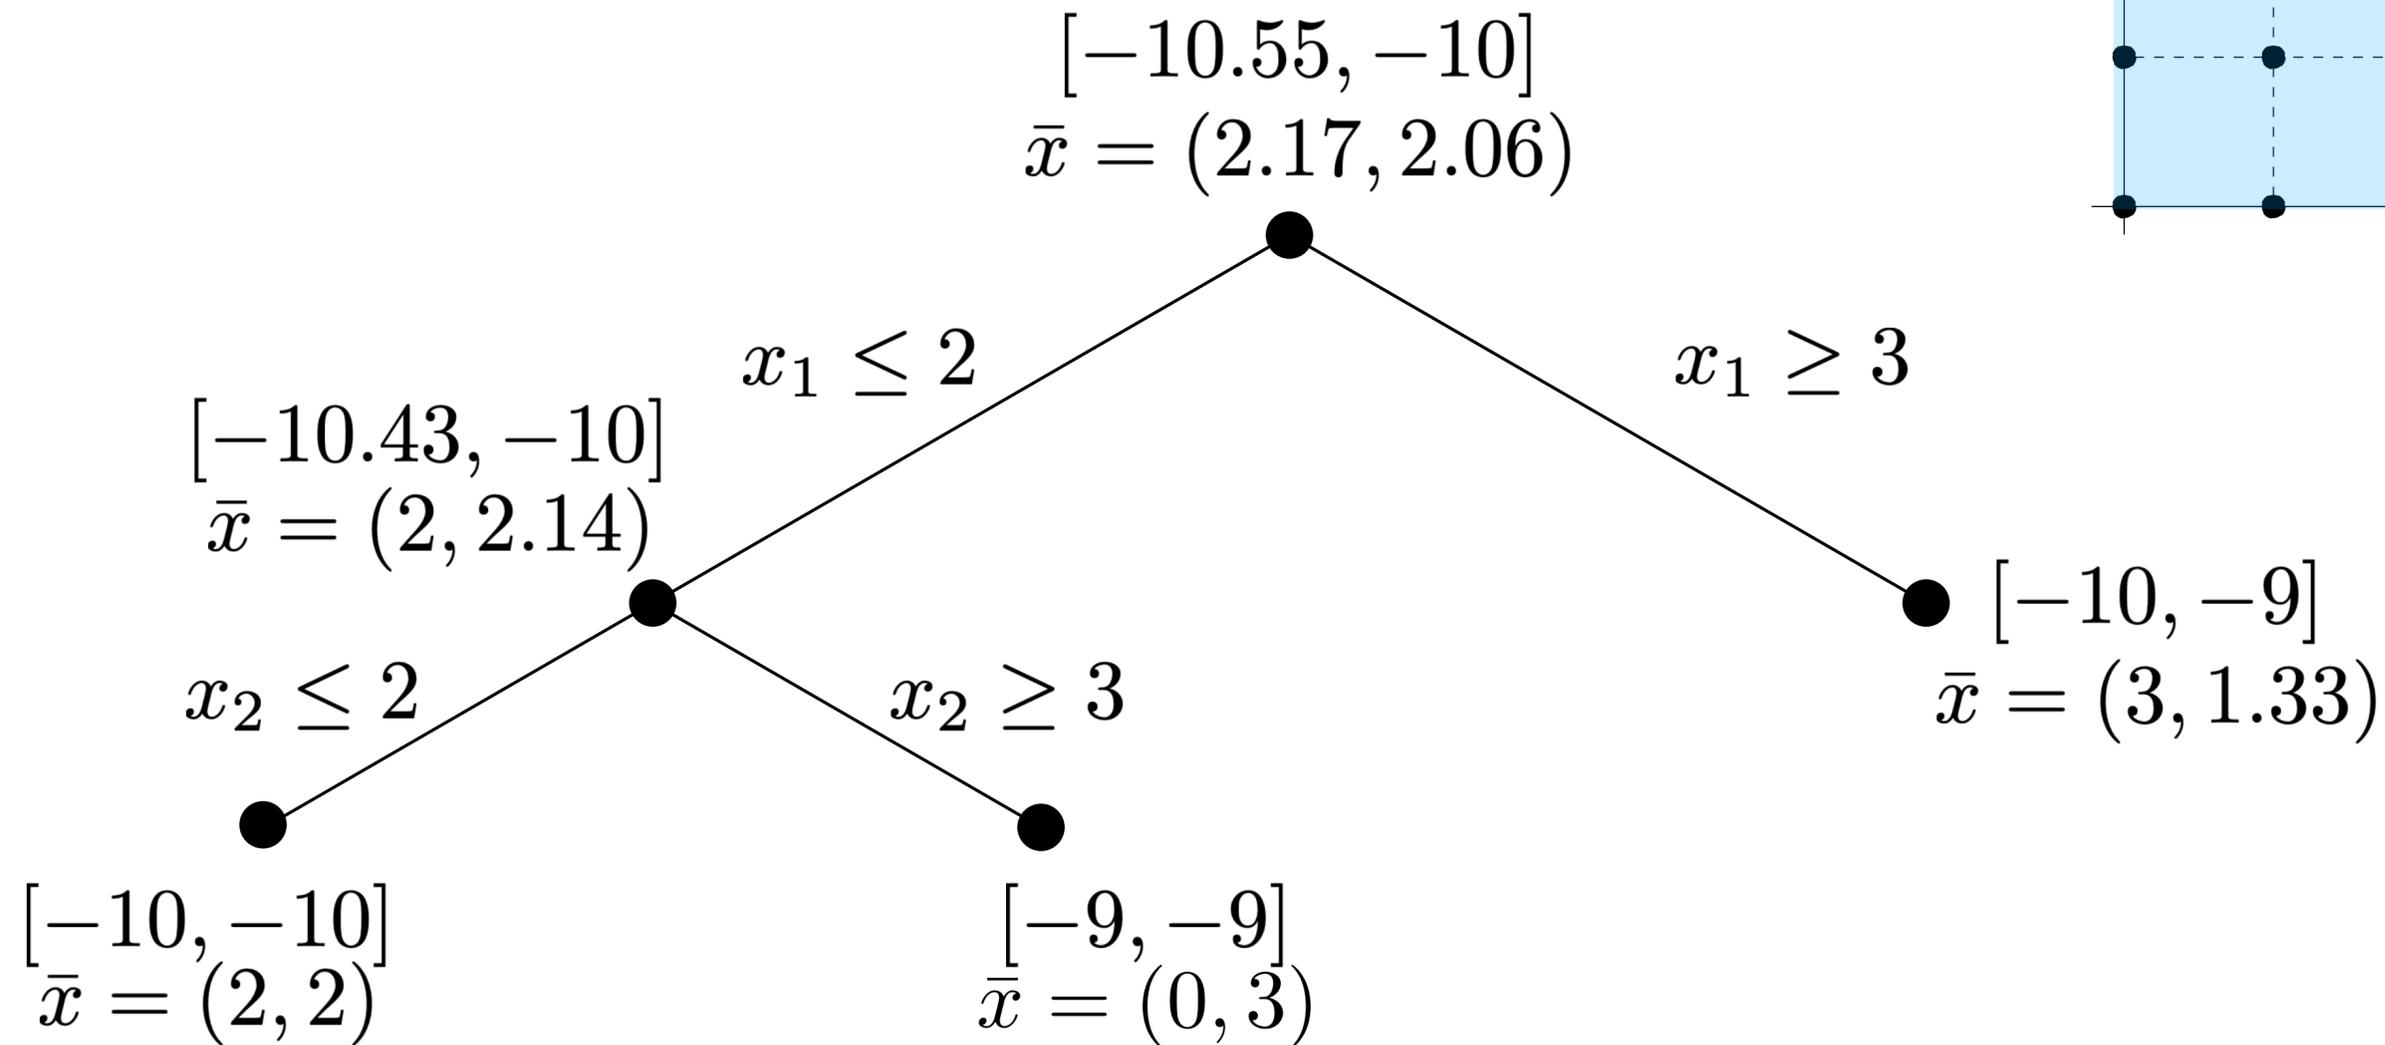

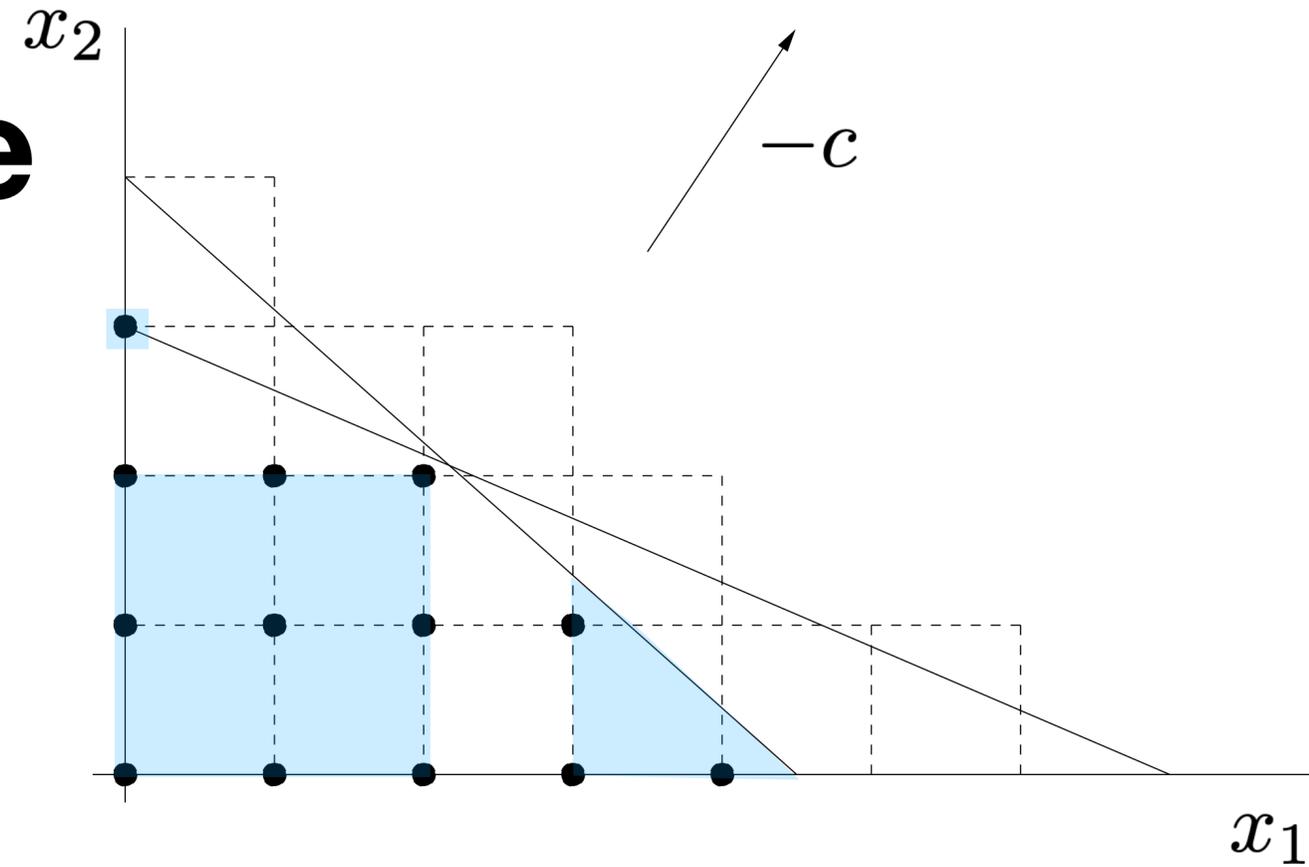

A larger example

minimize $\quad c^T x$

subject to $\quad Ax \le b$

$\qquad\qquad x \in \mathbf{Z}^n$

$m = 20$
$n = 10$
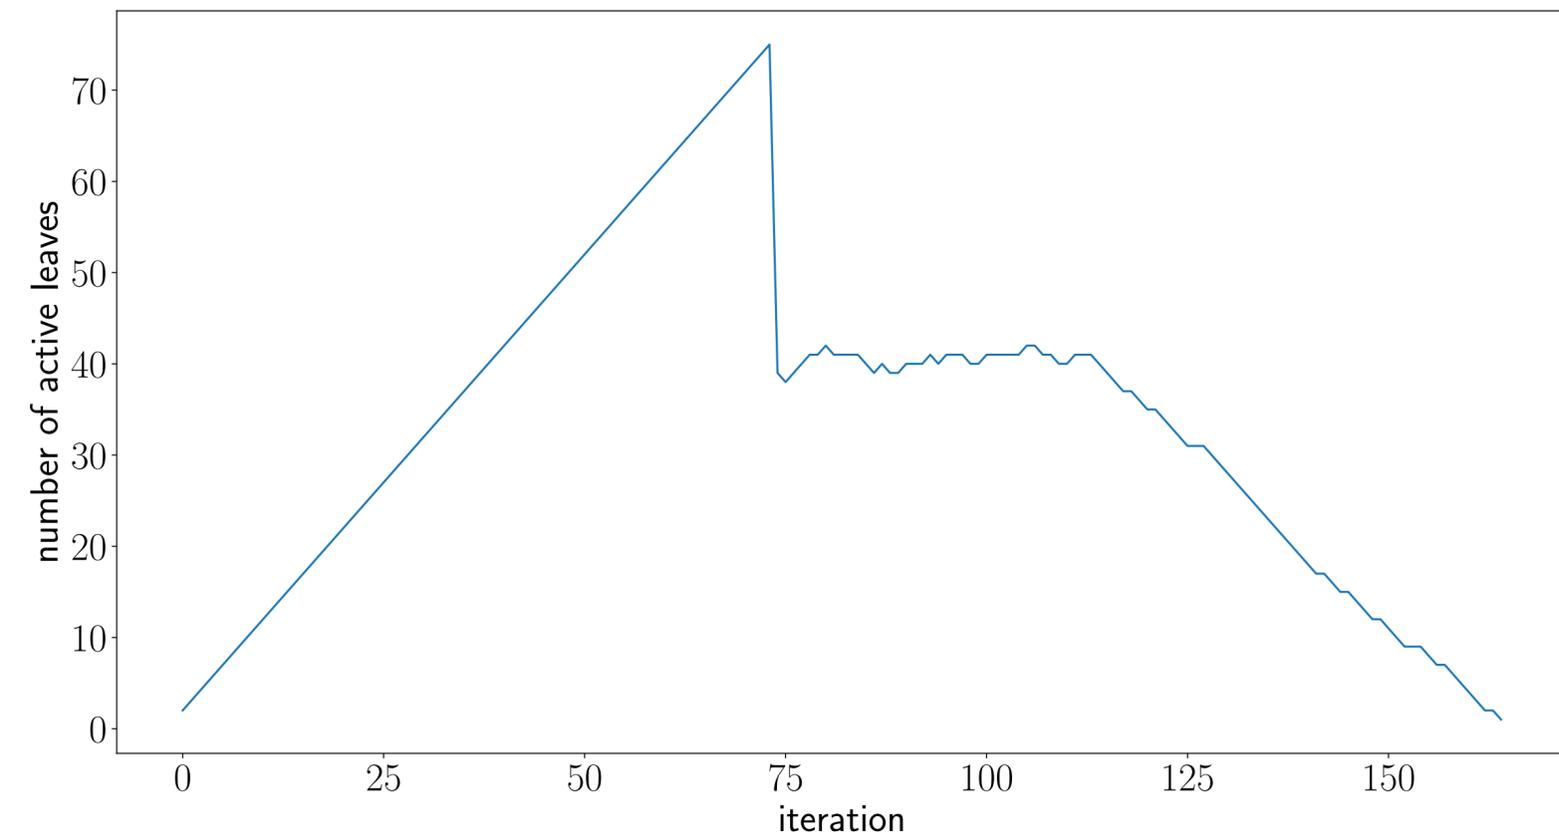

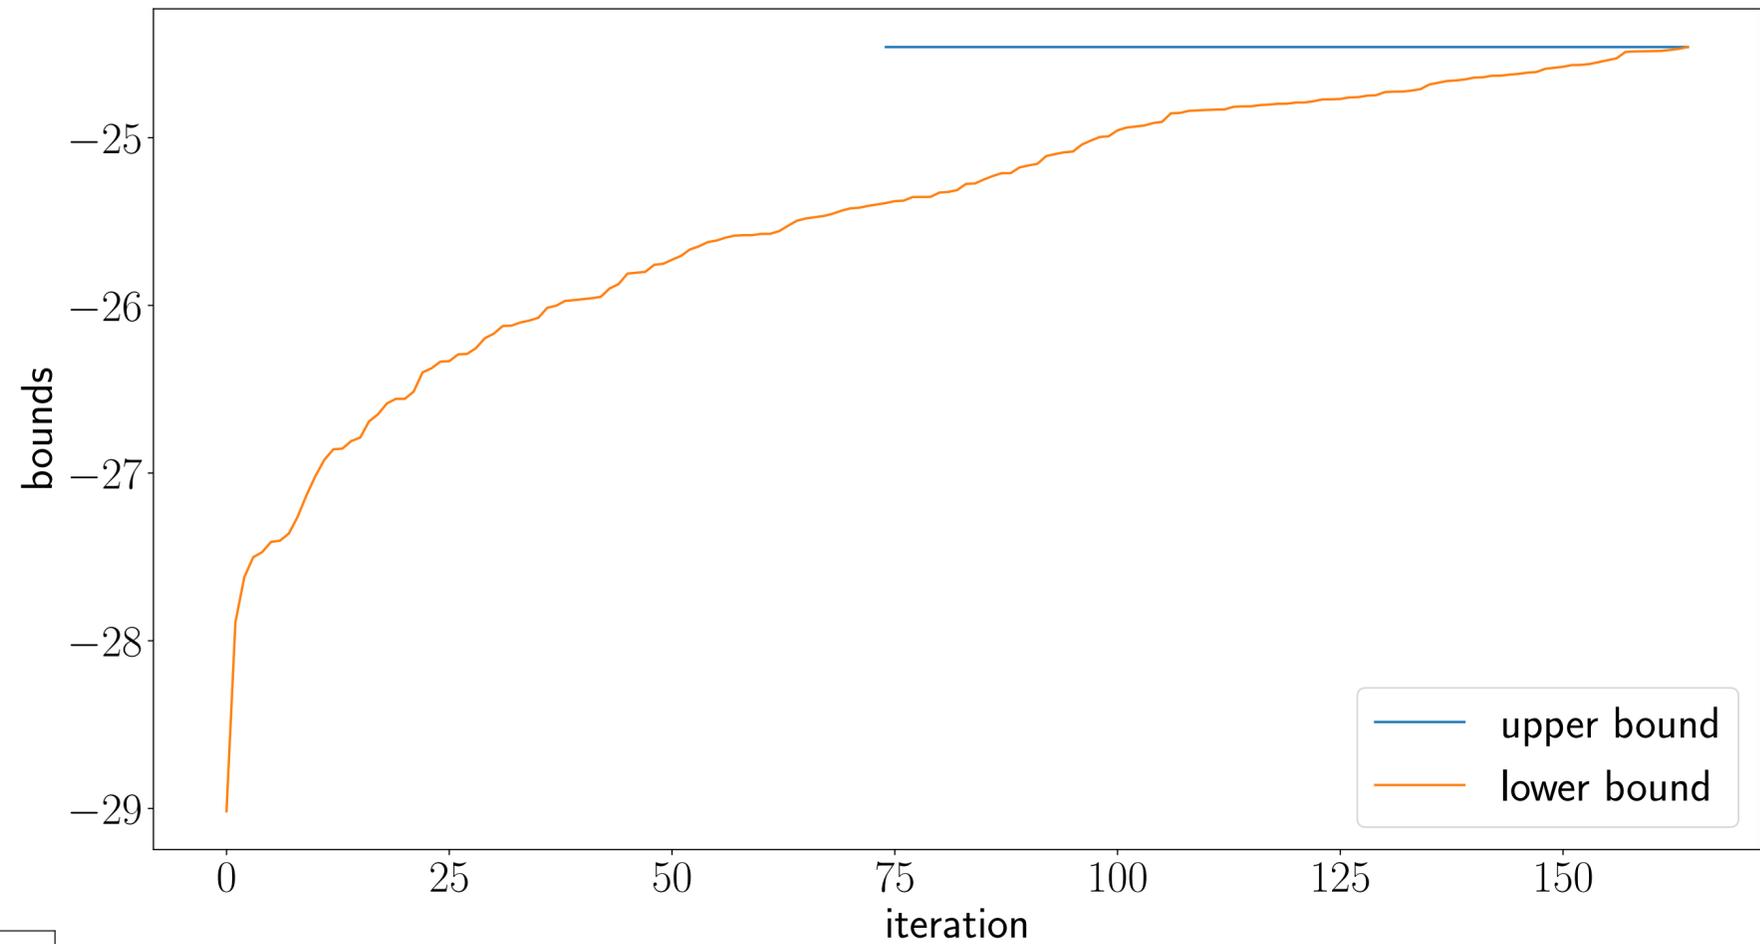

Cardinality minimization

Minimum cardinality example

Find sparsest x satisfying linear inequalities

$$\begin{array}{ll} \text{minimize} & \mathrm{card}(x) \\ \text{subject to} & Ax \leq b \end{array}$$

Equivalent mixed-boolean LP

$$\begin{array}{ll} \text{minimize} & \mathbf{1}^T z \\ \text{subject to} & l_i z_i \leq x_i \leq u_i z_i, \quad i = 1, \dots, n \\ & Ax \leq b \\ & z \in \{0, 1\}^n \end{array}$$

Big-M formulation

- l_i, u_i are lower/upper bounds on x_i
- The tightness of l_i, u_i can greatly influence convergence

27

Computing big-M constants

l_i is the optimal value of

$$\begin{aligned} \text{minimize} \quad & x_i \\ \text{subject to} \quad & Ax \leq b \end{aligned}$$

u_i is the optimal value of

$$\begin{aligned} \text{maximize} \quad & x_i \\ \text{subject to} \quad & Ax \leq b \end{aligned}$$

Total
$2n$ LPs

Remarks

- If $l_i > 0$ or $u_i < 0$ we can just set $z_i = 1$
  (we cannot have $x_i = 0$)
- This procedure, called "bound tightening", is very common in the pre-processing step of modern solvers

Cardinality problem relaxation

minimize $\mathbf{1}^T z$

subject to $l_i z_i \leq x_i \leq u_i z_i, \quad i = 1, \ldots, n$

               $Ax \leq b$

               $0 \leq z \leq 1$

1-norm minimization

If $u_i = -l_i = M$, then

$-M z_i \leq x_i \leq M z_i \quad \Rightarrow \quad (1/M)|x_i| \leq z_i \quad \longrightarrow$

    minimize $(1/M)\|x\|_1$

    subject to $Ax \leq b$

**Relaxation is fancier version
of 1-norm minimization**
(induces sparsity)

Implementation details

Upper bound $\mathrm{card}(\bar{x})$ with $\bar{x}$ from the relaxation (1-norm induces sparsity)

Lower bound we can replace L with $\lceil L \rceil$ since card is integer valued

Best-bound search split node with lowest L

Most ambivalent variable the closest z_j to $1/2$

Small example

Data

40 variables, 200 constraints

$2^{40} \approx 1$ trillion combinations

Results

- Finds good solution very quikcly
- Weighted 1-norm heuristic works very well
- Terminates in 54 iterations
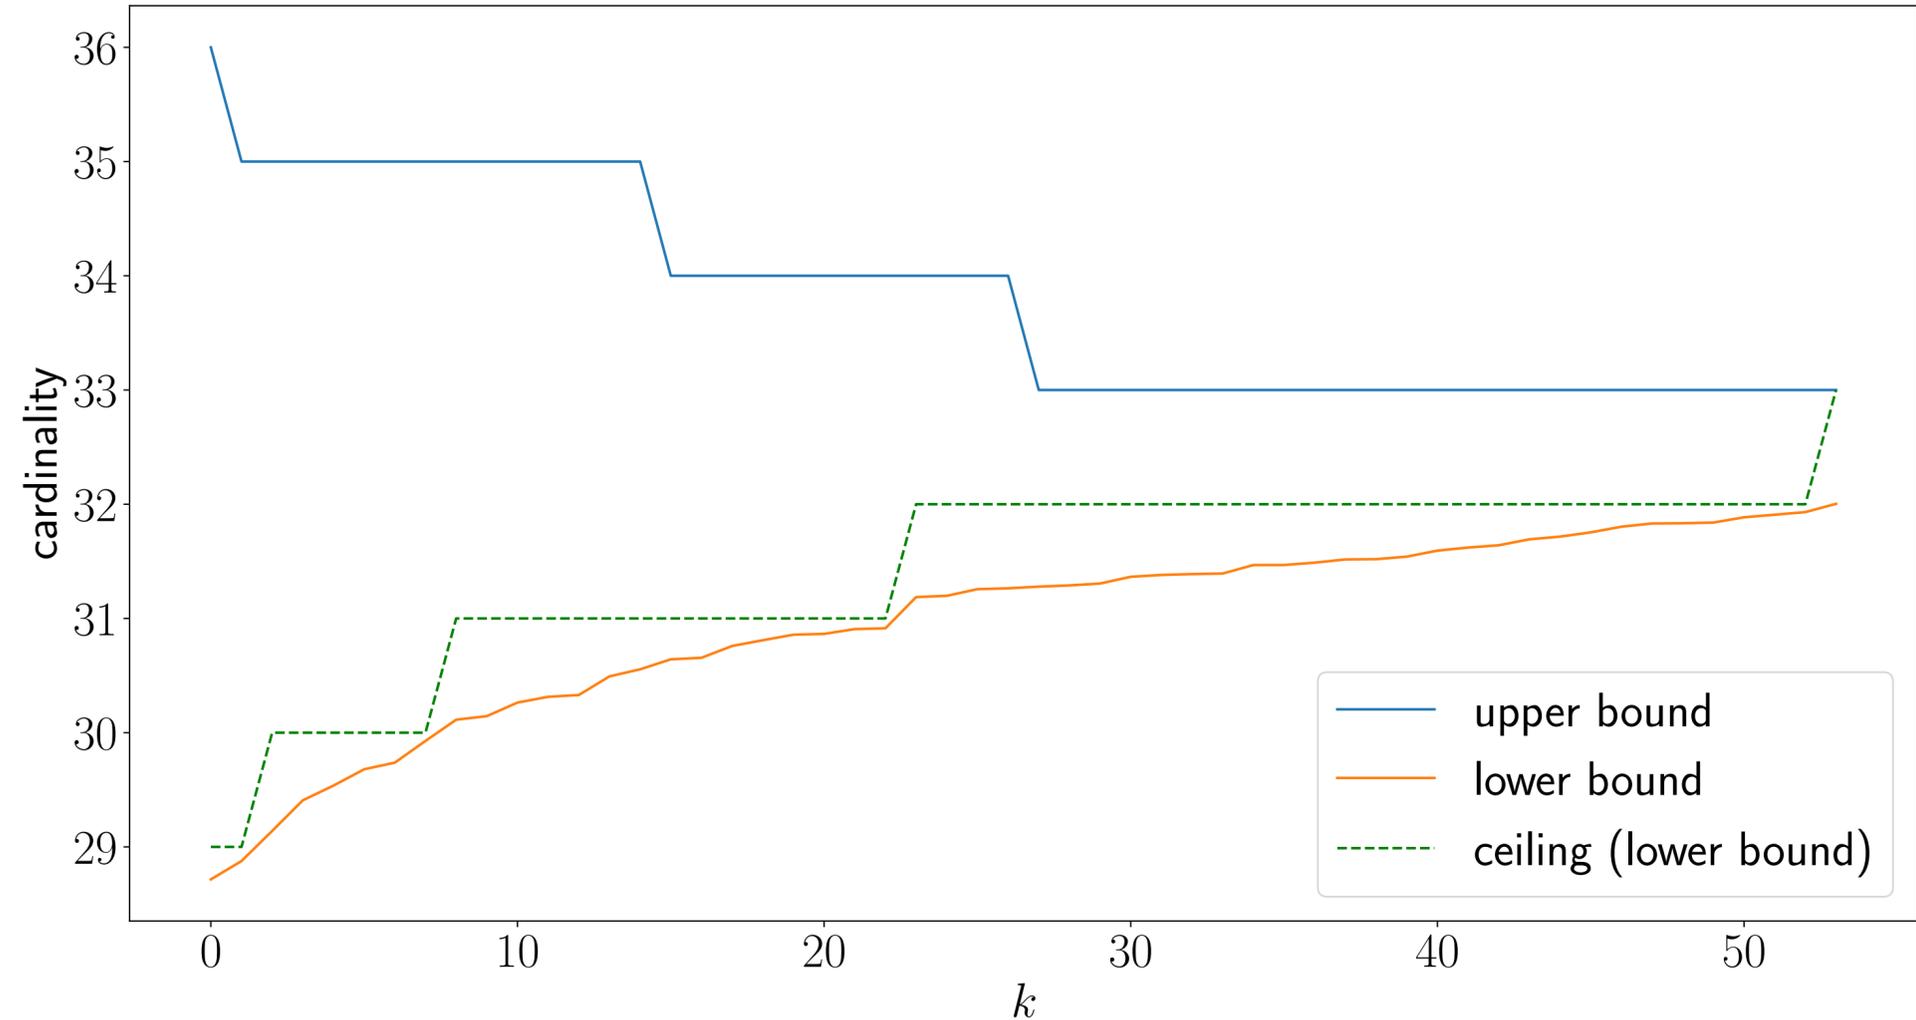

Medium example

Data

60 variables, 200 constraints

$2^{60} \approx 1.15 \cdot 10^{18}$ combinations

Results

- Finds good solution very quikcly
- Weighted 1-norm heuristic works very well
- Terminates in ≈ 1200 iterations
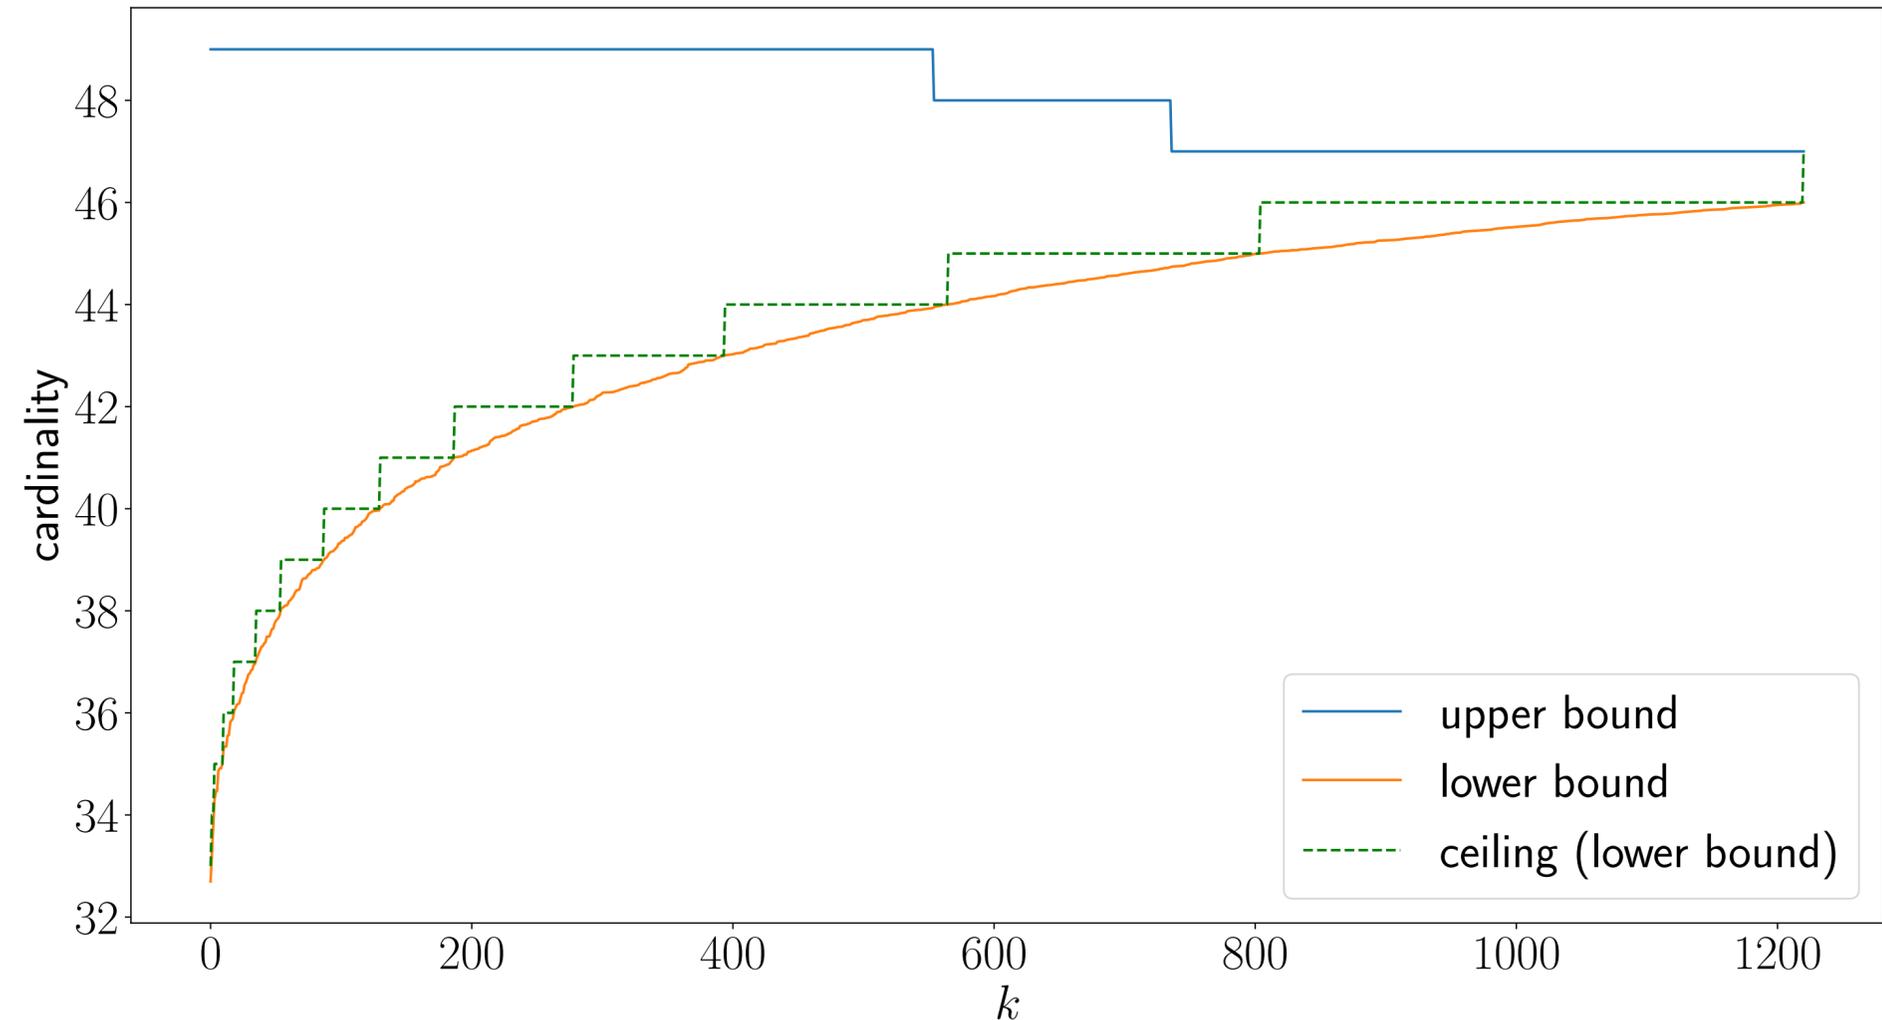

Larger example

Data

100 variables, 300 constraints

$2^{100} \approx 1.26 \cdot 10^{30}$ combinations

Results

- Finds good solution very quikcly
- 6 hours run, no termination
- Only optimality gap $U - L$ in the end
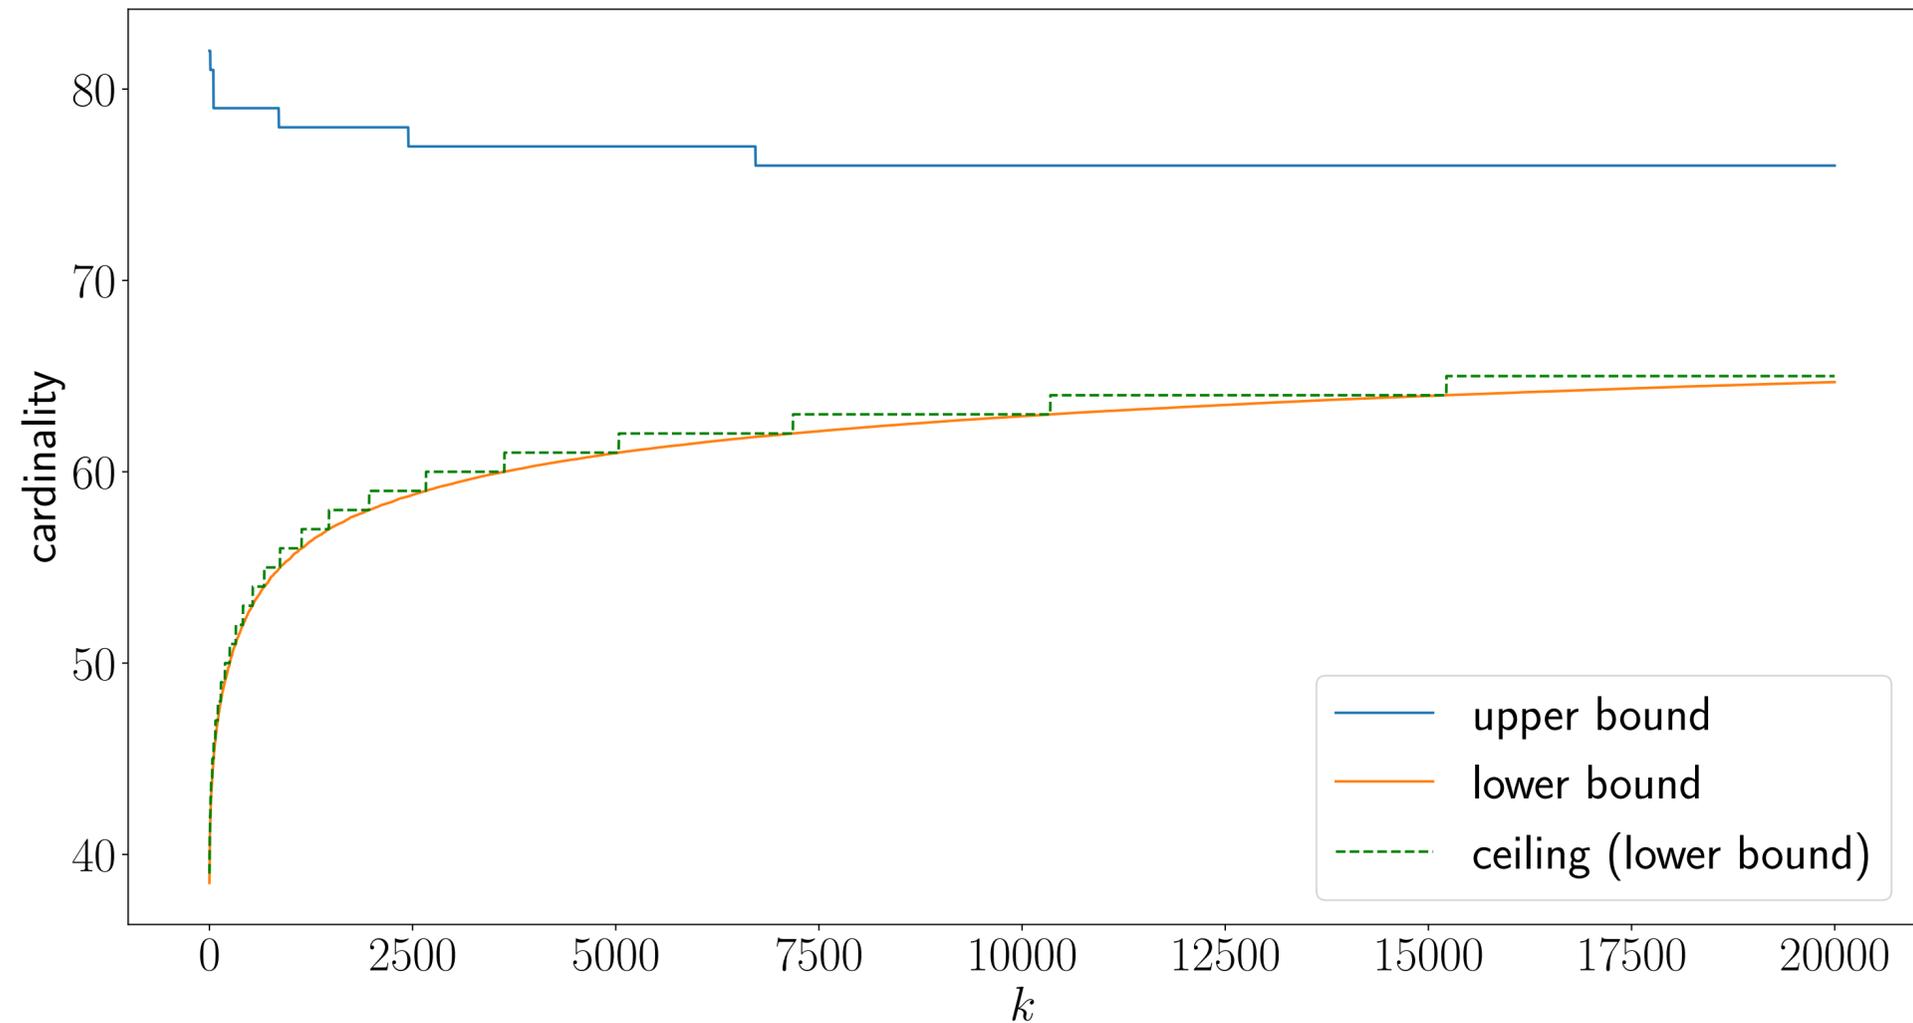

Larger example with commercial solver

Gurobi output

Data

100 variables, 300 constraints

$2^{100} \approx 1.26 \cdot 10^{30}$ combinations

Results

- Optimal cardinality 72
- Much more sophisticated method
- 1888 seconds (31 minutes) run (very slow!)

```

```

Tree size can grow dramatically

Example for 360 seconds on CPU…

10,000 nodes

[Mixed-integer nonlinear optimization, Belotti, Kirches, Leyffer, Linderoth, Luedtke, Ashutosh]
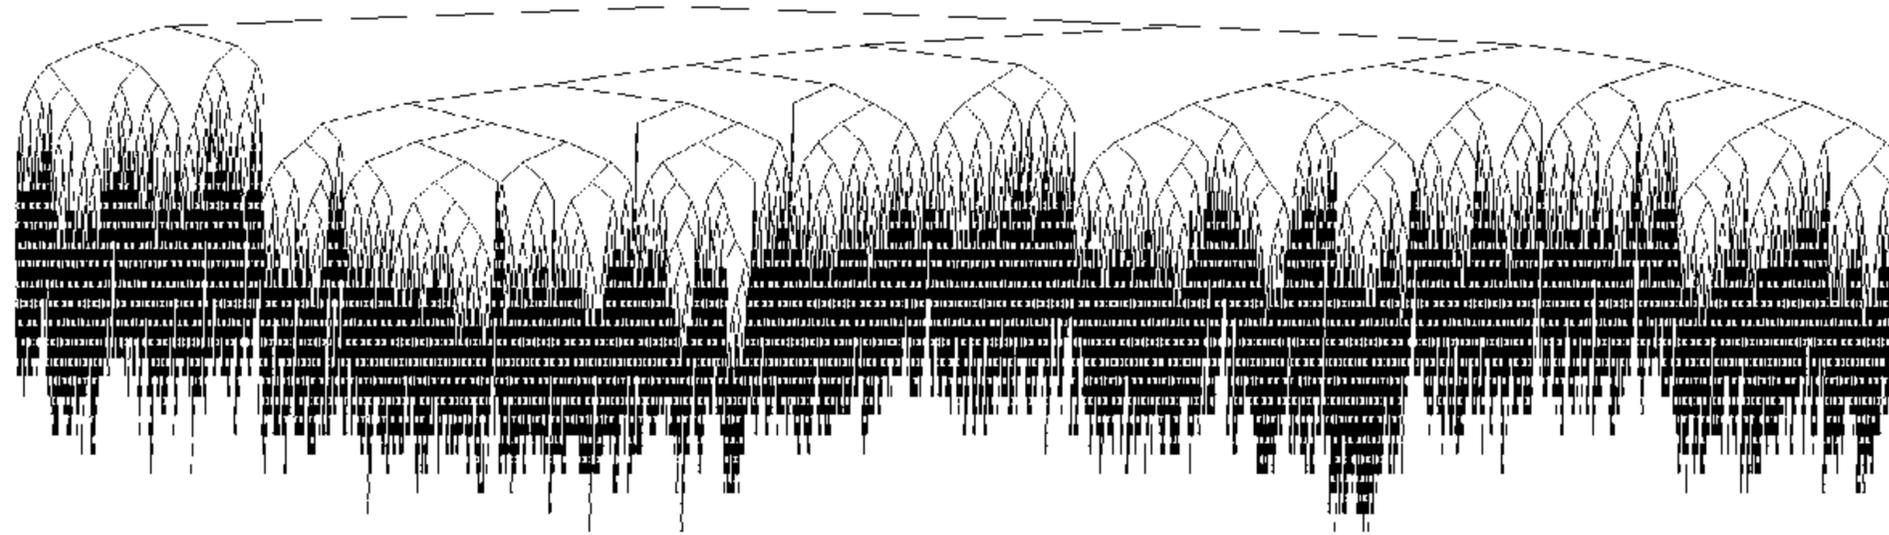

Progress of mixed-integer optimization

Top500 peak CPU power
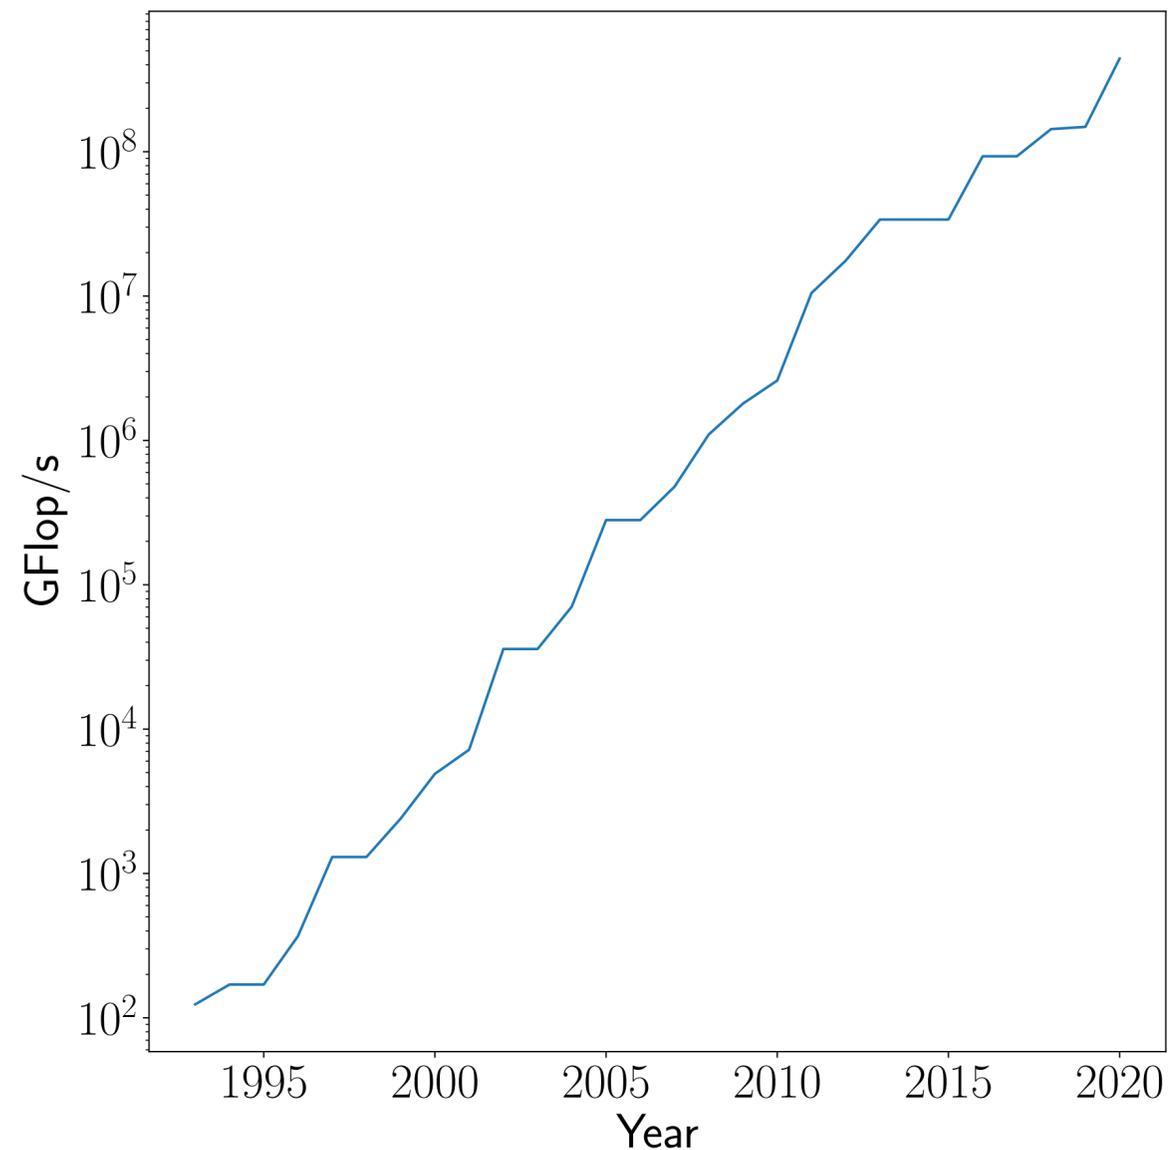

Hardware speedups

4 mln x

Software speedups

100,000 x

400 billion times speedups!

400,000 years → 30 seconds

Branch and bound algorithms

Today, we learned to:

- **Develop** branch and bound iterations to solve mixed-integer optimization

- **Understand** the rules and the practical implications in branch and bound

- **Solve** small numerical examples

- **Apply** branch and bound to a cardinality-constrained optimization

Next lecture

- The role of optimization
