STANDARD FORM

- Problem sizes in different formulations. What is  $m$ ?
- Vector  $x$  is a basic solution if and only if there exists  $m$  columns of  $A$  being linearly independent. I'm just wondering what if there aren't  $m$  independent columns, what does it mean? Also, what does it mean if there're multiple sets of independent columns. Does it have any geometric meaning, like any relationship with the extreme points in polyhedron?

$$c^T d = c_B^T d_B + \sum_{i \in N} c_i d_i = \sum_{i \in N} (\overbrace{c_i - c_B^T A_B^{-1} A_i}^{\bar{c}_i}) d_i = \sum_{i \in N} \bar{c}_i d_i$$

# Optimality conditions

## Proof

For a basic feasible solution  $x$  with basis  $B$  the reduced costs are  $\bar{c} \geq 0$ .

Consider any feasible solution  $y$  and define  $d = y - x$

Since  $x$  and  $y$  are feasible, then  $Ax = Ay = b$  and  $Ad = 0$

$$Ad = A_B d_B + \sum_{i \in N} A_i d_i = 0 \quad \Rightarrow \quad d_B = - \sum_{i \in N} A_B^{-1} A_i d_i$$

$N$  are the  
nonbasic indices

The change in objective is

$$c^T d = c_B^T d_B + \sum_{i \in N} c_i d_i = \sum_{i \in N} (c_i - c_B^T A_B^{-1} A_i) d_i = \sum_{i \in N} \bar{c}_i d_i$$

Since  $y \geq 0$  and  $x_i = 0, i \in N$ , then  $d_i = y_i - x_i \geq 0, i \in N$

$$c^T d = c^T (y - x) \geq 0 \quad \Rightarrow \quad c^T y \geq c^T x.$$
